Keywords:
Pig
Respiratory disease
Systems dynamics model
Financial performance
Marketing contracts

Pigmeat is the most consumed red meat globally and consumption is expected to continue to increase. The sector is faced by the risk of epidemic and endemic disease impacts and other adverse influences. The aim of this study was to develop a dynamic simulation model of pig growing and finishing that can be used to model the financial and economic impacts of a variety of scenarios both related to disease effects and other influences on production. The model consists of a physical performance module and financial performance module. The core of the physical performance module comprises three stocks to model the flow of pigs from purchase to slaughter. Mortality rates, daily live weight gain and feed conversion ratios influence the dynamics of the physical performance. Since contracts between farmers and slaughterhouses often include large price penalties for over- and underweight pigs, carcase weight distribution is an important determinant of revenues. The physical performance module, therefore, simulates slaughter weight variations. The financial performance module calculates revenue, costs and gross margins. The revenue calculations take into account price penalties for over- and underweight pigs. To demonstrate the capabilities of the model, we apply the model to assess the economic consequences of production impacts associated with respiratory disease. We use estimated production impacts associated with respiratory disease from a study of all-in-all out growing and finishing systems based on pig production data and information from slaughterhouse monitoring in the UK. Our model suggests a reduction in the gross margin of nearly 40 % as a consequence of the estimated production impacts associated with a 10% increase in respiratory disease prevalence. Due to the lack of reliable information on slaughter weight variation, we also simulate the model using different assumptions about the slaughter weight distribution. An increase in the standard deviation of carcase weights from 8 kg to 12 kg, holding average weights constant, more than halves gross margins under our scenarios. We suggest that for all-in-all-out systems, carcase weight variation is likely to be a substantial factor in reducing income in the presence of respiratory disease and the economic impact of respiratory disease may be underestimated if the effects of disease on variation in carcase weights are not included in any analysis.

Importancia económica de las enfermedades respiratorias

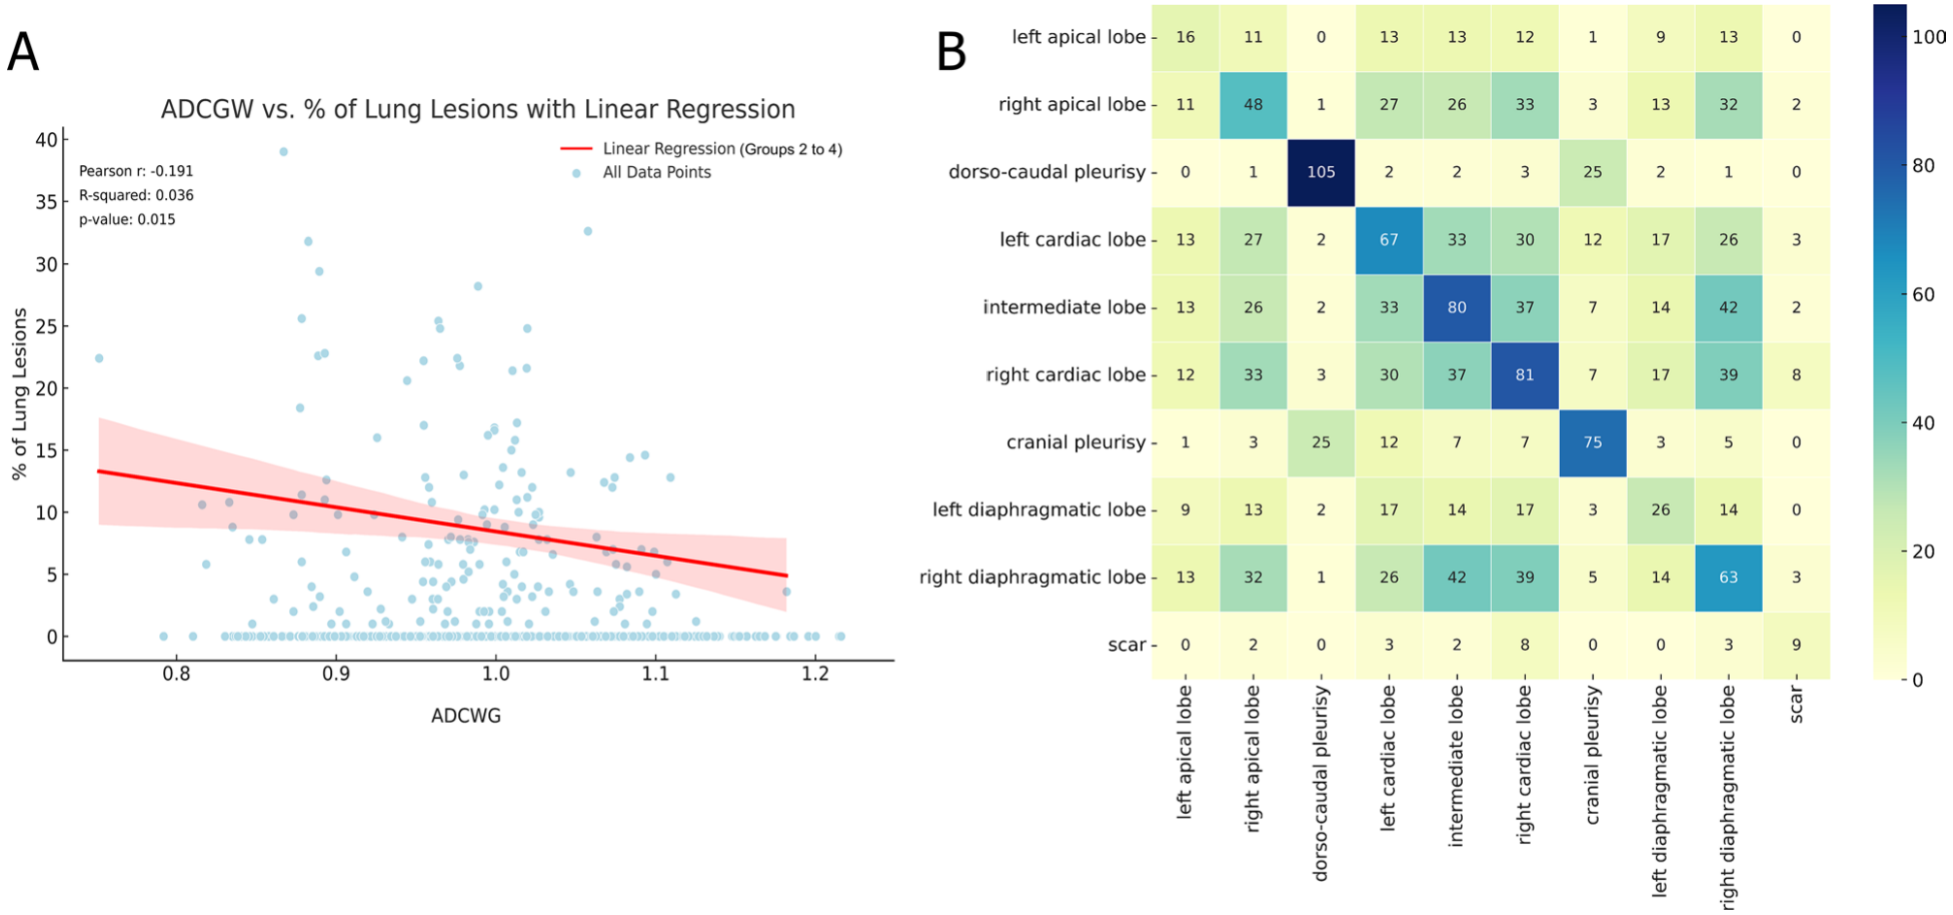

Figure 2 Relationship Between Average Daily Carcass Weight Gain (ADCWG) and Lung Lesions in slaughter-age pigs from 7 different batches. (**A**) The scatter plot shows the percentage of lung lesions against ADCWG with a linear regression line. (**B**) The co-occurrence matrix illustrates the frequency of the different types of lung lesions present together in various lobes and regions of the lungs, with a color gradient representing the count of co-occurrences

Przyborowska et al. BMC Veterinary Research (2024) 20:554

Importancia económica de las enfermedades respiratorias

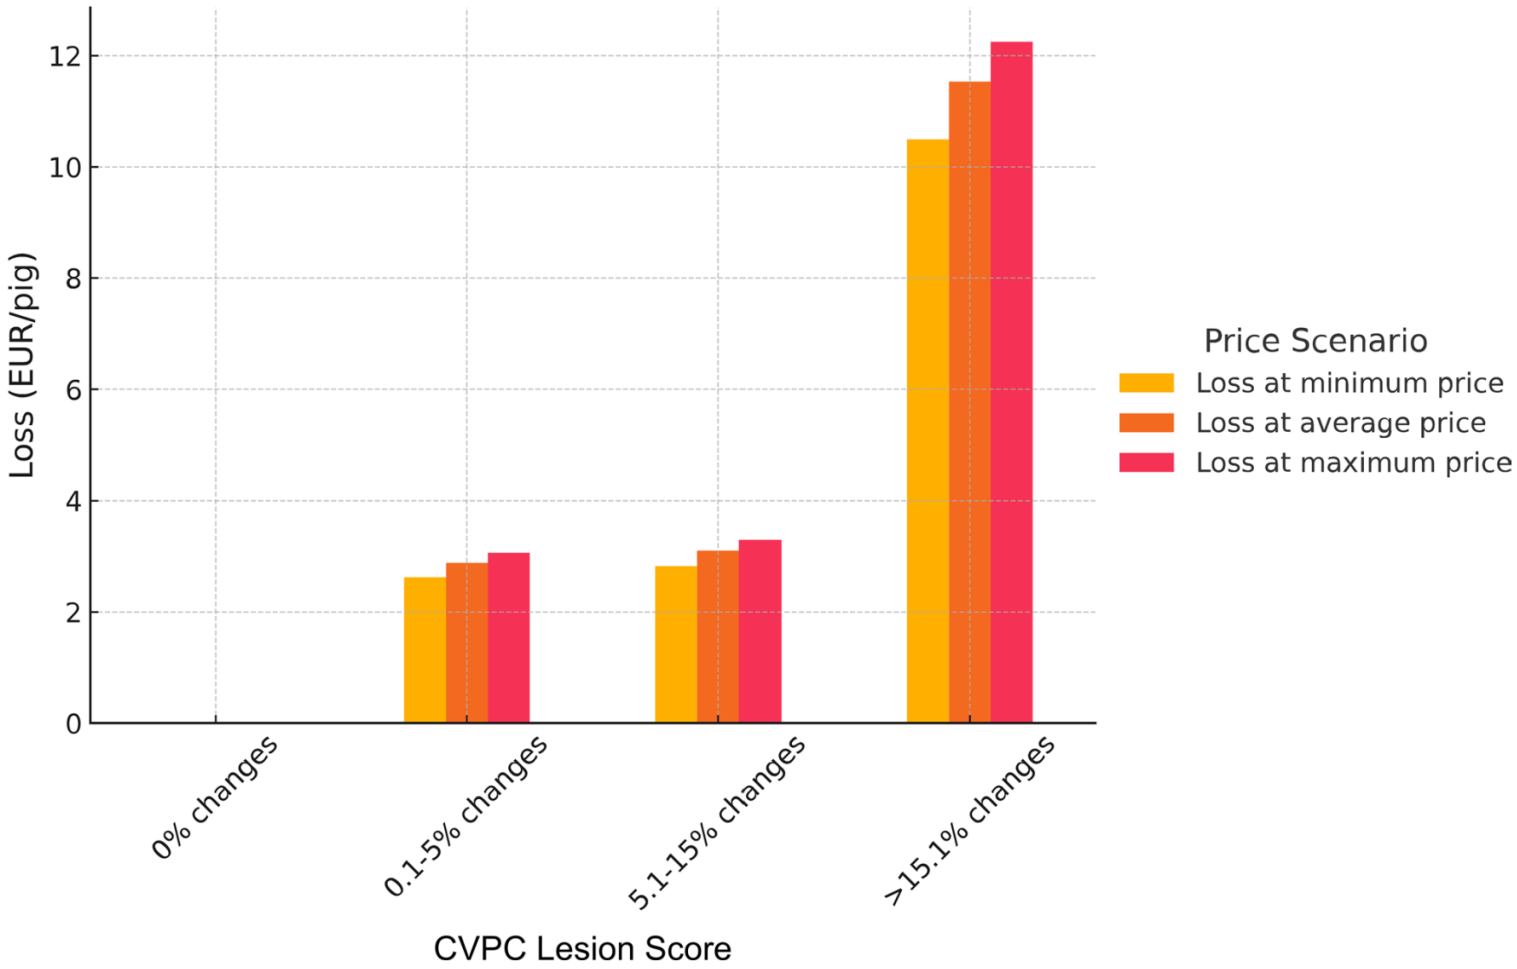

Figure 4 Economic losses depending on the degree of cranio-ventral pulmonary consolidation (CVPC) and price scenarios. The bar chart illustrates the economic losses per affected pig (in EUR) associated with varying degrees of CVPC scores under three price scenarios: minimum (201.86 EUR/100kg), average (221.77 EUR/100kg), and maximum (235.59 EUR/100kg). The x-axis categorizes the pigs into four groups based on the percentage of CVPC lung changes: 0% changes (reference), 0.1-5% changes, 5.1–15% changes, and ≥ 15.1% changes

Table 4 Studies assessing the impact of cranioventral pulmonary consolidation (CVPC) on average daily gain (ADG) in pigs.

References	Study population	Impact on ADG	Comment
Presence of CVPC			
[59]	23 studies	10 publications: no effect 13 publications: decrease	
[51]	9 studies	−17%	Feed conversion ratio +14% High correlation between decreased ADG and feed conversion ratio
[36]	2 farms (578 pigs)	Farm A: −26 g Farm B: −26 g	
[54]	14 farms (6,997 pigs)	−38 g (−4.9%)	Large differences between farms (range: −7% to +2.6%
[69]	39 farms	No effect	No effect on feed conversion ratio Performance data were analysed at farm level; lung lesions were assessed on one subgroup (35 pigs per farm) at slaughter
[8]	1 farm (108 pigs)	−9%	
Severity of CVPC			
[51]	5 studies	37.4 g per 10% of affected lung tissue	Five studies
[52]	21 pigs	20% CVPC throughout lifetime: 25 kg lower weight at slaughter	Radiographic monitoring of the lungs from 21 to 180 days of age 25 days extra to reach slaughter weight
[7]	2 farms (41 lungs)	41.1 g/day for 10% affected lung volume	10% affected lung leads to 16.7 days more to reach 104.5 kg
[70]	2 farms (58 lungs)	31.4 g/day for 10% affected lung volume	10% affected lung leads to 13·2-days more to reach 104.2 kg Only significant association between lung lesion and ADG in one farm
[72]	1 farm (333 pigs)	2.2 g/day for each 1% of affected lung volume	1% affected lung leads to 0.61 days more to reach slaughter weight; early infections cause more performance loss
[50]	7 farms (18 cohorts with 30–35 pigs / cohort)	6.8 g/day for 1% of affected lung	Serologic testing was more effective than slaughter evaluation in assessing the impact of subclinical infection on ADG
[73]	1 farm (138 pigs)	Score 2: −45 g/day (−6%) Score 3: −90 g/day (−11%)	Lung consolidation: score 1: 0–5%; score 2: 6–40%; score 3: > 40% Score 2: 3.13 kg less at slaughter Score 2: 10.85 kg less at slaughter
[54]	14 farms (6,997 pigs)	−7.0 g/day (0.7%) for 1 point increase in severity score (1–28)	More ADG decrease in pigs with severe lesions: score 0: 775 g; scores 1–4: 750 g; scores 5–8: 735 g; score > 8: 695 g
[71]	1 farm (500 pigs)	1.8 g/day for each 1% of affected lung surface	Financial loss of §6.55 in pigs with more than 15% affected lung tissue compared to animals without lesions
[8]	1 farm (108 pigs)	−66.4 g/day in pigs with > 10% of affected lung surface versus pigs with no lesions:	Days to slaughter: + 8 days; carcass weight: −3.6 kg

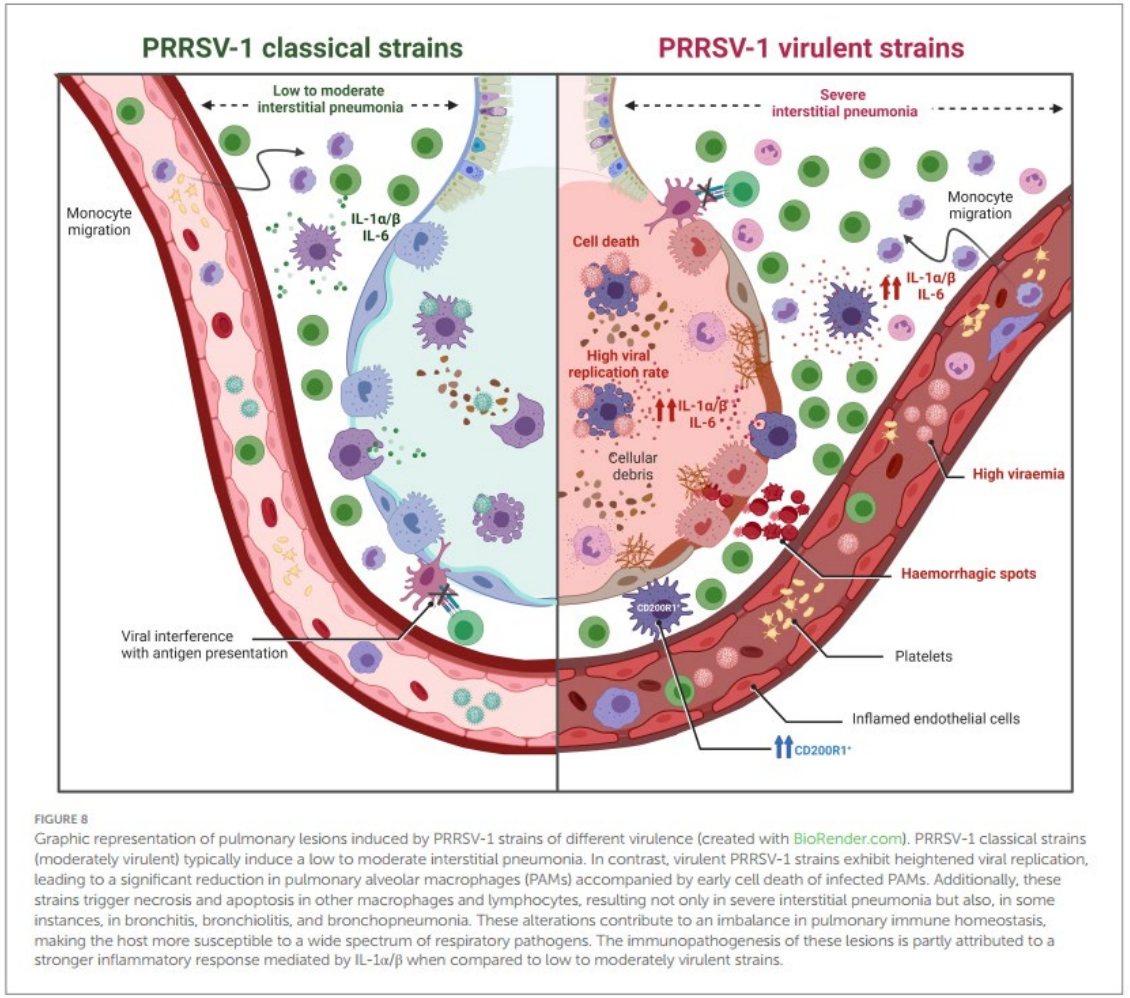

FIGURE 8
Graphic representation of pulmonary lesions induced by PRRSV-1 strains of different virulence (created with BioRender.com). PRRSV-1 classical strains (moderately virulent) typically induce a low to moderate interstitial pneumonia. In contrast, virulent PRRSV-1 strains exhibit heightened viral replication, leading to a significant reduction in pulmonary alveolar macrophages (PAMs) accompanied by early cell death of infected PAMs. Additionally, these strains trigger necrosis and apoptosis in other macrophages and lymphocytes, resulting not only in severe interstitial pneumonia but also, in some instances, in bronchitis, bronchiolitis, and bronchopneumonia. These alterations contribute to an imbalance in pulmonary immune homeostasis, making the host more susceptible to a wide spectrum of respiratory pathogens. The immunopathogenesis of these lesions is partly attributed to a stronger inflammatory response mediated by IL-1α/β when compared to low to moderately virulent strains.

Complejo respiratorio porcino: resultado de las coinfecciones

Coinfección SIV – *S. suis*

Carga vírica

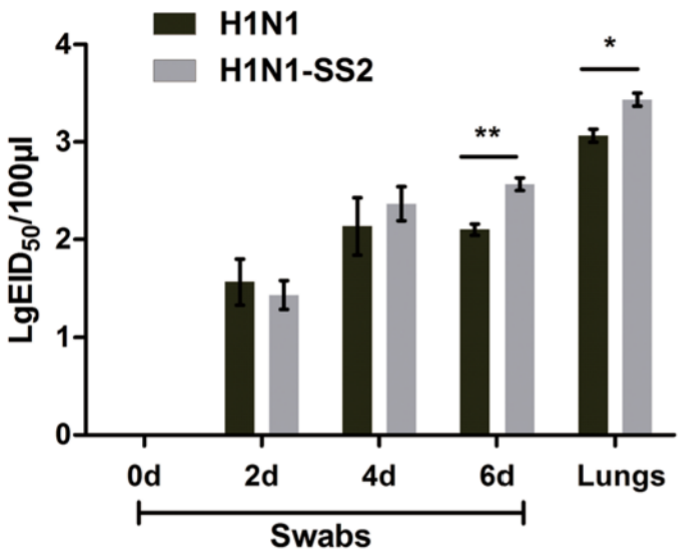

Fig 2. Virus isolation of nasal swabs and lungs in each group. Swabs were collected from the right nostrils of pigs from each group every other day. The obtained nasal swabs were inserted into vials containing 1.5 mL of sterile PBS. Supernatants were collected and viruses were qualified as $LgEID_{50}$. At the day 6 of the experiment, all pigs were humanely euthanized and lungs were collected and homogenized in sterile PBS and then centrifuged to collect the supernatant. Virus titer was quantified as $LgEID_{50}$. Data were showed as mean ± SEM by Student's t-test. *P*-value less than 0.05 was noted with a single-asterisk and p-value less than 0.01 was noted with a double-asterik.

Lesiones

Coinfecciones virus - bacterias

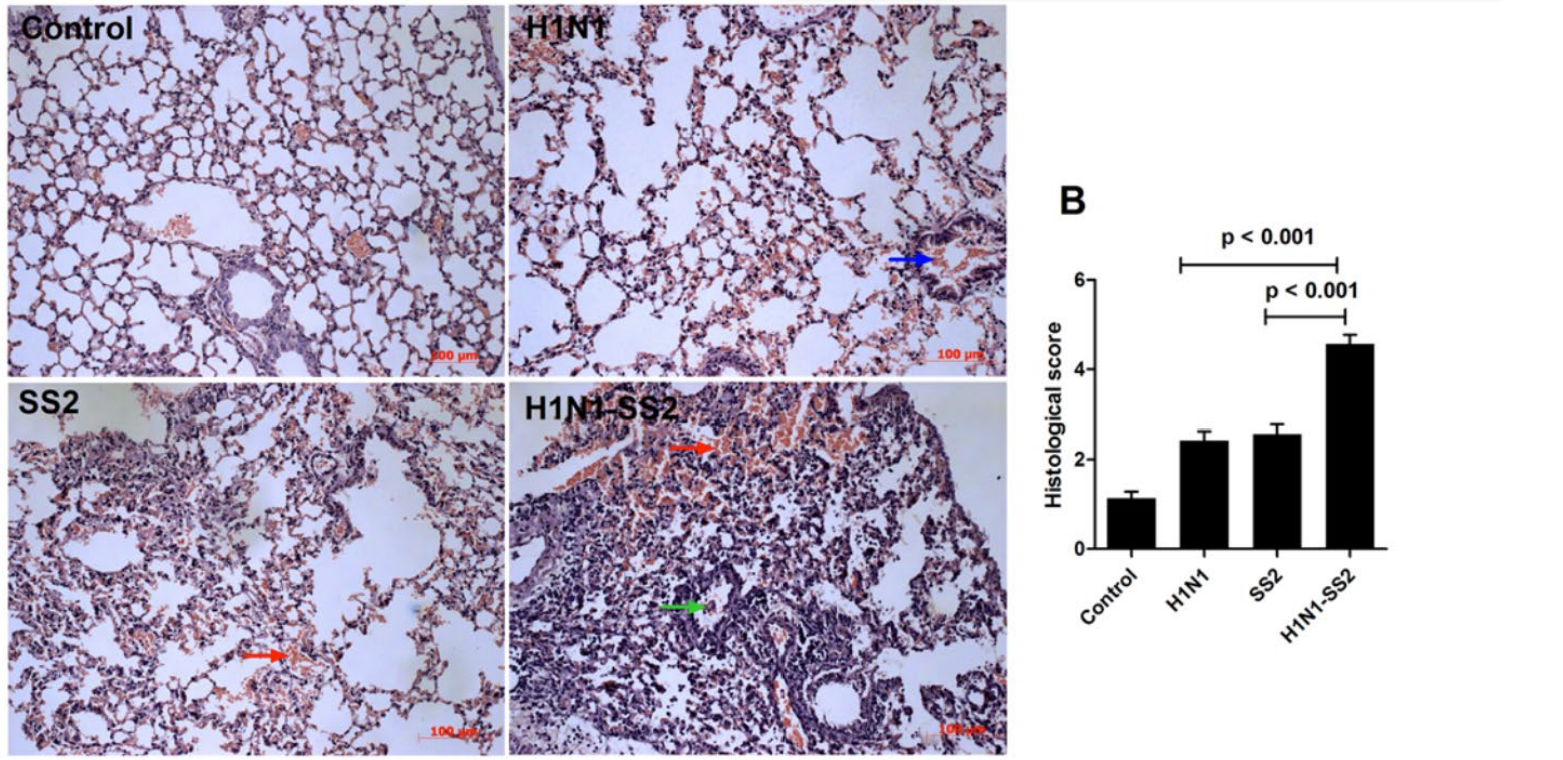

Fig 1. Histopathologic changes in lungs of infected pigs. Pigs were PBS-control infected or infected with H1N1, SS2 and H1N1-SS2 as described in methods. On day 6 of the experiment, lungs were removed and underwent Hematoxylin and eosin stain. (A) The microscopic lesions of lung tissues from each group showed different extent of acute pneumonia with pathological changes: alveolar wall thickening, bleeding (red arrow), debris in the lumen (green arrow), erythrocyte effusion (blue arrow), and the accumulation of inflammatory cells. (B) Histological score of sections of lungs in pigs from each group were showed as mean ± SEM by two-tailed Student's t-test. *P*-value less than 0.05 was considered to represent a statistically significant difference.

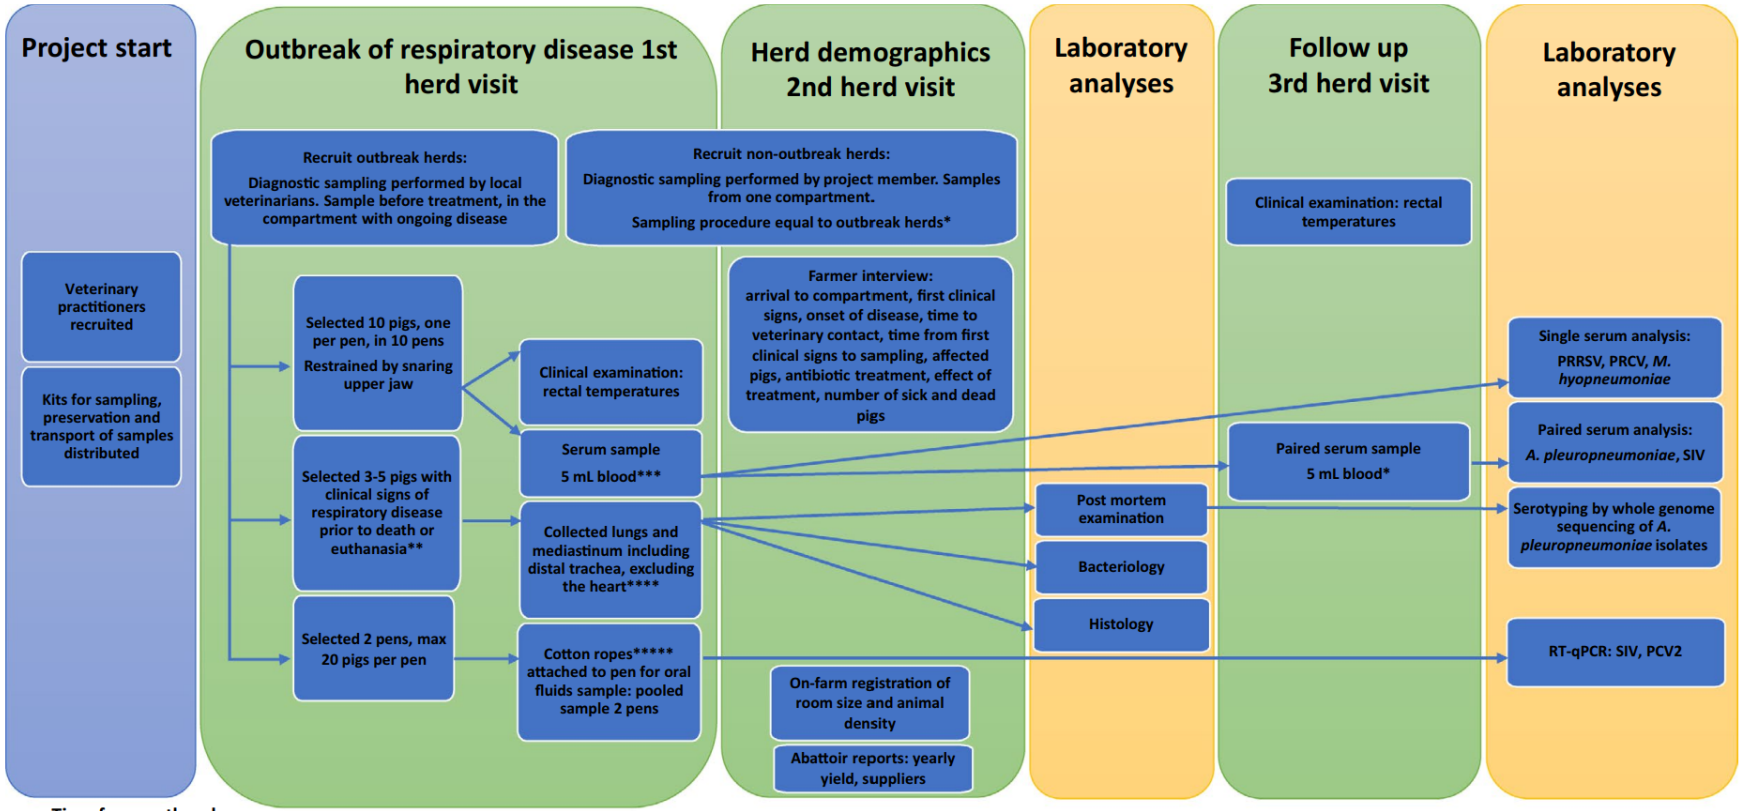
Diagnóstico de las enfermedades respiratorias

Aproximaciones al diagnóstico de las alteraciones respiratorias

¿Cómo abordar el diagnóstico de las enfermedades respiratorias?



A. pleuropneumoniae=Actinobacillus pleuropneumoniae, SIV=Swine Influenza virus, PRRSV=Porcine Reproductive and Respiratory Syndrome Virus, PRCV=Porcine Respiratory Corona Virus, M. hyopneumoniae=Mycoplasma hyopneumoniae, RT-qPCR = Real Time quantitative Polymerase chain reaction, PCV2=Porcine Circovirus type 2.
All sampled material where stored in sealed containers wrapped in absorbent wrapping, packed with cold packs in Styrofoam box and shipped by express overnight shipping to The Norwegian Veterinary Institute.
** Non-outbreak herds: organ sampling from animals without clinical signs of respiratory disease.*
*** By captive bolt and exsanguination.*
**** Vacuette® 9 mL Z Serum Clot Activator, Greiner Bio-One 18G needles. Centrifuged at 2500 rpm for 5 minutes. Serum extracted and kept at -20˚C until analysis.*
*****.Refrigerated at approximately 4 degrees Celsius until examination 1-3 days after evisceration.*
****** Unbleached cotton rope. Sample extracted into clean collection bag and sampling vial. Oral fluids kept at -20˚C until analysis.*

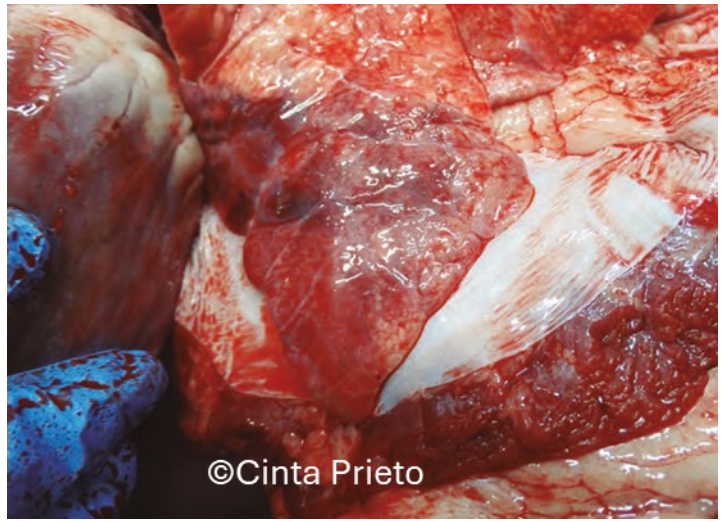
Lesiones

Bronconeumonía catarral (purulenta)

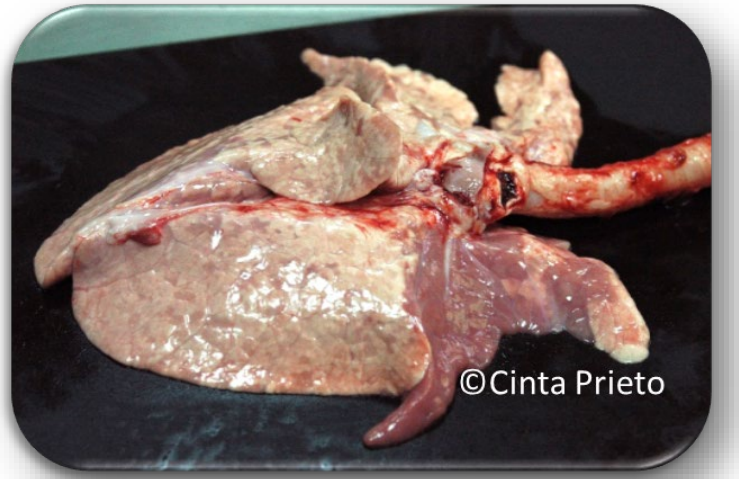
⇩

Vía de entrada: aerógena



Observaciones macroscópicas:

- Distribución cráneo-ventral
- Elevado grado de consolidación
- Clara demarcación entre tejido afectado y tejido normal
- Exudado purulento en vías respiratorias



Lesiones microscópicas:

- Inflamación de los espacios broncoalveolares
- Infilración de neutrófilos
- Abundante exudado en vías respiratorias y alveolos

Agentes causales más habituales:

- ***Bordetella bronchiseptica***
- ***Pasteurella multocida***
- ***Mesomycoplasma hyopneumoniae (neumonía enzoótica)***

Aproximaciones al diagnóstico de las alteraciones respiratorias

Sospecha clínica

Pleuroneumonía fibrinosa o fibrinonecrotizante

⇩

Vía de entrada: aerógena

Lesiones

<u>Observaciones macroscópicas</u>:

- Distribución cráneo-ventral o dorsocaudal (APP)
- Daño tisular extenso. Con frecuencia necrosis del tejido pulmonar
- Exudación y/o fibrina en la superficie pleural

<u>Lesiones microscópicas</u>:

- Engrosamiento de los tabiques interlobulillares,
- Presencia de fibrina y neutrófilos en bronquios, bronquiolos y alvéolos
- Áreas de necrosis coagulativa,
- Pleuritis fibrinosa.
- Casos crónicos:
  - Secuestros pulmonares, Adherencias pleurales

Agentes causales más habituales:

- ***Actinobacillus pleuropneumoniae***
- ***Bordetella bronchiseptica (bronconeumonía necrótico-hemorrágica)***

Aproximaciones al diagnóstico de las alteraciones respiratorias

Sospecha clínica

Pleuroneumonía fibrinosa o fibrinonecrotizante

Lesiones

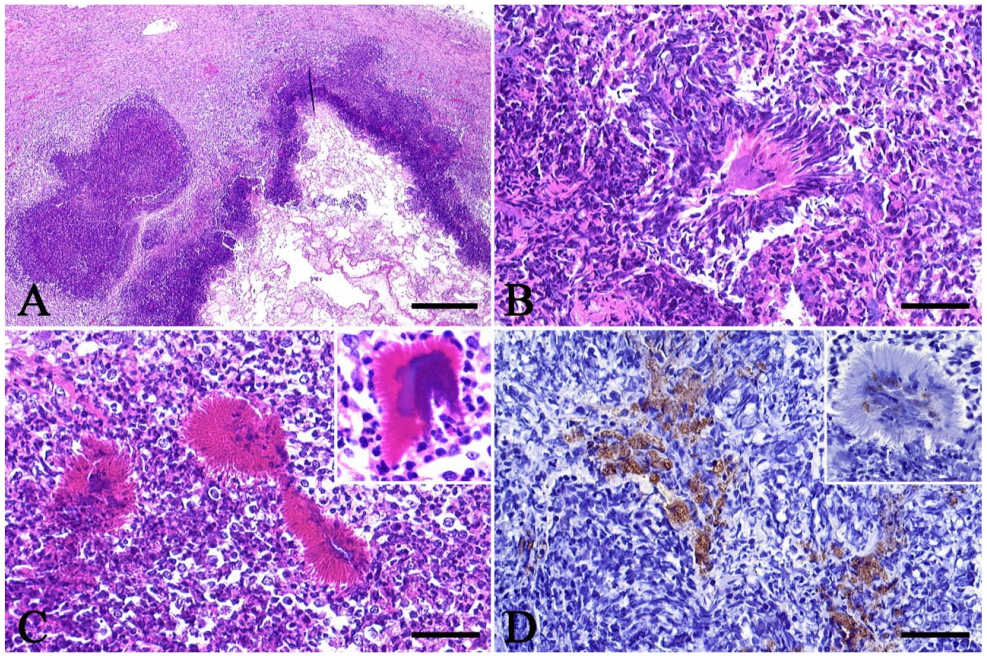


Fig. 2. Histopathologic features of pneumonia. Pig No. 699. (**A**) Multifocal abscesses with central necrosis are encapsulated with granulation tissue. Hematoxylin and eosin (HE). Bar=400 µm. (**B**) Numerous neutrophils infiltrate around the necrotic area. Oat cells surround the bacterial cells. HE. (**C**) Asteroid bodies in the inflammatory foci. Eosinophilic amorphous material with radiating club-shaped configurations is deposited around the bacterial cells (inset, higher magnification). HE. (**D**) The bacterial cells are immunolabeled with antiserum raised against *Actinobacillus pleuropneumoniae* serovar 15 (inset, higher magnification of the asteroid body). Immunohistochemistry. Bars (B–D)=40 µm.

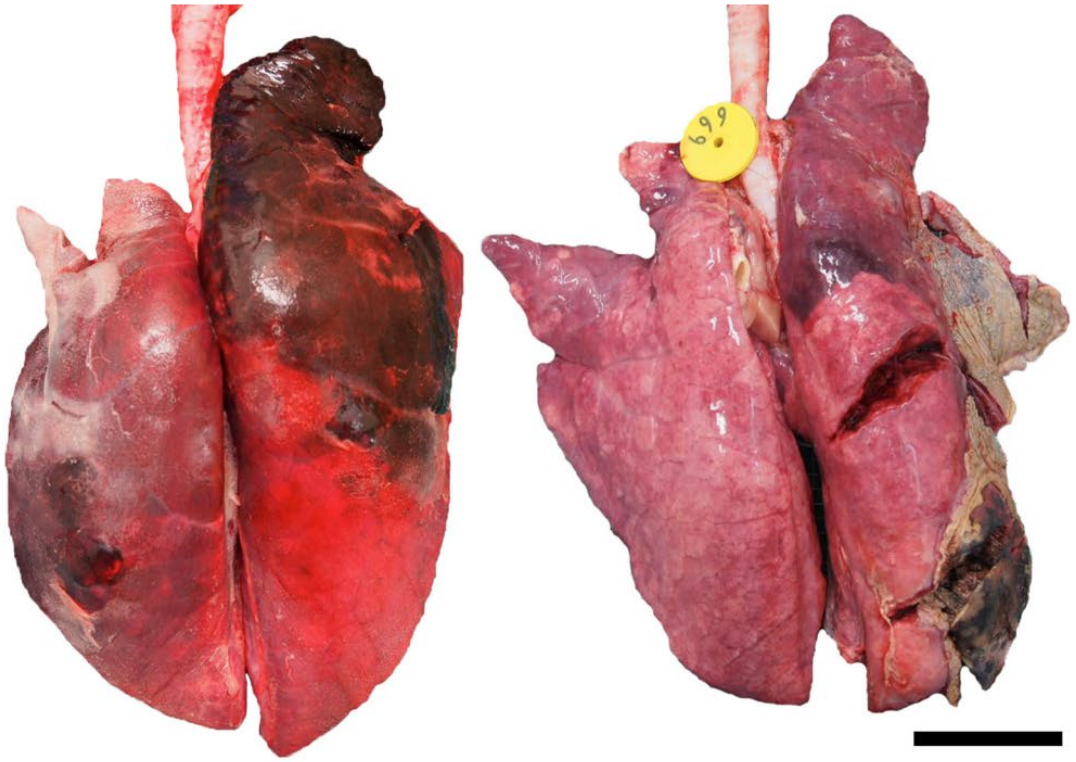

Fig. 1. Gross lesions of lungs. In the pig No. 695 (left side), the lung is swollen, and severe hemorrhages are observed in the right anterior and middle lobes and left caudal lobe. The surfaces of the left lobes are partially covered with fibrin. In the pig No. 699 (right side), severe hemorrhages and fibrin deposition are observed in the right middle and caudal lobes. Bar=5 cm.

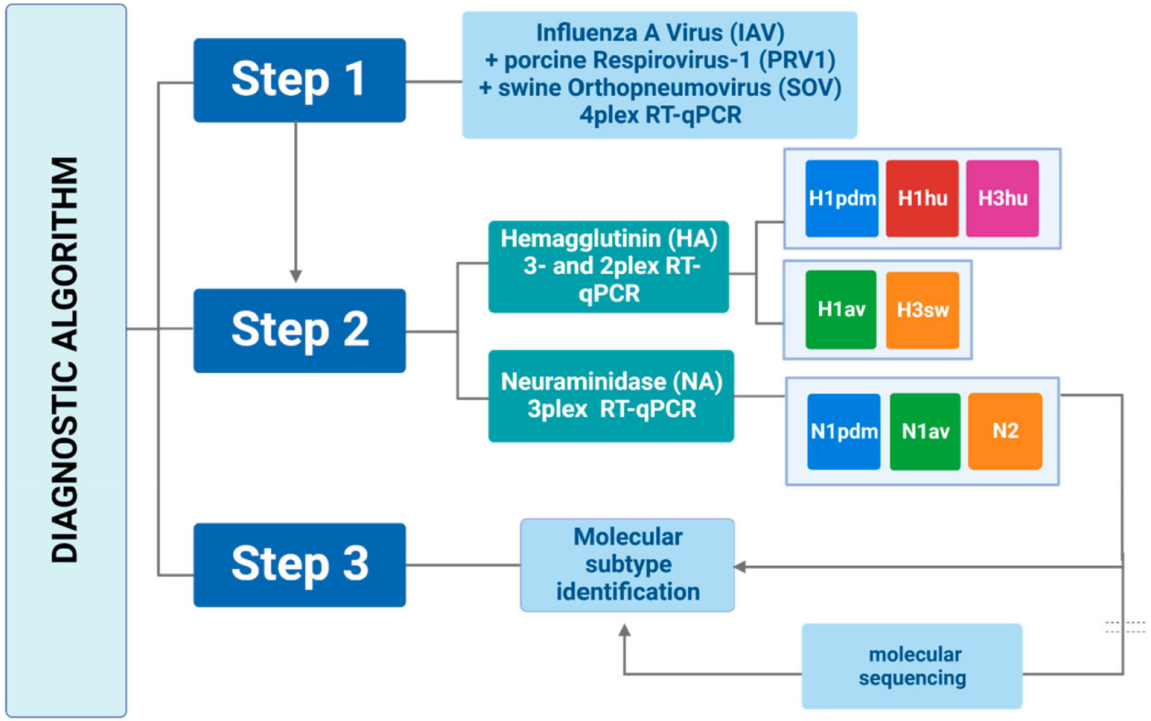

Figure 1. Diagnostic algorithm based on one-step multiplex RT-qPCRs for detection and subtyping of swine influenza A viruses (swIAV) as well as the detection of porcine respirovirus 1 and swine orthopneumovirus circulating in European pig populations. Step 1 depicts a tetraplex RT-qPCR, targeting the M-gene segment of (sw)IAV, the F-gene of PRV1 and the NP-gene of SOV; an internal control (IC2) is essentially included in this tetraplex RT-qPCR (not shown). In step 2, subtyping for IAV RNA-positive samples is attempted employing the one-step duplex- and triplex HA- and the triplex NA-specific RT-qPCRs developed in this study. Step 3 is only required in case if HA or NA subtype/lineage cannot be assigned by the shown RT-qPCRs: HA and/or NA amplicons need to be generated by conventional one-step RT-PCR for Sanger amplicon or minION sequencing and BLAST searches or swine H1 clade classification by Anderson, Macken [57] on the Influenza Research Database (IRD) to finalize subtyping of swIAV.

Sero- and *apx*-typing of German *Actinobacillus pleuropneumoniae* field isolates from 2010 to 2019 reveals a predominance of serovar 2 with regular *apx*-profile

Lukas Schuwerk[1,2*], Doris Hoeltig[3], Karl-Heinz Waldmann[3], Peter Valentin-Weigand[1] and Judith Rohde[1]

Abstract

Serotyping is the most common method to characterize field isolates of *Actinobacillus (A.) pleuropneumoniae*, the etiological agent of porcine pleuropneumonia. Based on serology, many farms seem to be infected and antibodies against a wide variety of serovars are detectable, but, so far it is unknown to what degree respective serovars contribute to outbreaks of clinical manifest disease. In this study, 213 German *A. pleuropneumoniae* field isolates retrieved for diagnostic purposes from outbreaks of porcine pleuropneumonia between 2010 and 2019 were genetically serotyped and analyzed regarding their *apx*-toxin gene profile using molecular methods. Serotyping revealed a prominent role of serovar 2 in clinical cases (64% of all isolates) and an increase in the detection of this serovar since 2010 in German isolates. Serovar 9/11 followed as the second most frequent serovar with about 15% of the isolates. Furthermore, very recently described serovars 16 (n = 2) and 18 (n = 8) were detected. Most isolates (93.4%) showed *apx*-profiles typical for the respective serovar. However, this does not hold true for isolates of serovar 18, as 75% (n = 6) of all isolates of this serovar deviated uniformly from the "typical" *apx*-gene profile of the reference strain 7311555. Notably, isolates from systemic lesions such as joints or meninges did not harbor the complete *apxICABD* operon which is considered typical for highly virulent strains. Furthermore, the extremely low occurrence (n = 1) of NAD independent (biovar II) isolates in German *A. pleuropneumoniae* was evident in our collection of clinical isolates.

Table 3 Overview of pleurisy scoring systems in slaughter pigs[a]

Score	Scoring system				
	Madec and Kobisch [57]	CTPA [b]	Pointon et al. [66]		SPES [c]
0	No pleurisy				
1	Interlobular pleurisy (visceral pleurisy)	Fibrinous pleurisy	Interlobular pleurisy (adhesions between lung lobes)	1 N: pleurisy with normal lungs 1P: pleurisy with pneumonic lungs	Cranioventral lesion: interlobar pleurisy or at ventral border of caudal lobes
2	Localized pleurisy < 2 cm diameter	Extended pleurisy: lungs cannot be removed from the carcass	Pleurisy (adhesions of lungs to chest wall)	2 N: pleurisy with normal lungs 2P: pleurisy with pneumonic lungs	Dorsocaudal monolateral focal lesion
3	Extensive pleurisy > 2 cm diameter with adhesions to ribcage	–	–		Bilateral lesion of type 2 or extended monolateral lesion (at least one third of one diaphragmatic lobe)
4	Partial or total ribcage condemnation	–	–		Severely extended bilateral lesion (at least one third of both diaphragmatic lobes)

[a] The Danish system [41] is explained in the text but not listed in the table, as it differs significantly from the other systems
